Summary

C-GMA – capability based GMA

- ▶ C-GMA goal: *define GMA-based open framework to build monitoring infrastructures.*
- ▶ Why to extend GMA?
 - ▶ GMA goal “*minimal specification that will support required functionality and allow interoperability*” not achieved
 - ▶ despite being are GMA-compliant, implementations are not interoperable
 - ▶ diversity of requirements – no single implementation can fulfill all.

C-GMA main concepts

- ▶ specialized components co-exist in single infrastructure
- ▶ they may cooperate when necessary or profitable

Summary

Another metadata dimension

Capability dimension

- ▶ distinguish the same data type with different constraints
 - ▶ find optimal source of data for particular purpose
 - ▶ enforce interoperability (eg. compatible protocols only)
- ▶ Both dimensions are taken into account when looking for matching party

Capabilities and attributes

- ▶ **capabilities** – component metadata
 - ▶ component properties (*persistent, trustworthy*)
 - ▶ interaction constraints (*protocol X*)
- ▶ **attributes** – event metadata
 - ▶ labels on data items – GMA events
 - ▶ expected handling of data (*sensitive* – pass to trustworthy component only)
 - ▶ data properties
- ▶ capabilities and attributes may refer to each other

Summary

C-GMA components

- ▶ producer, consumer, directory – inherited from GMA
- ▶ **mediator** – perform two-dimensional matching

Summary

Two layer specification

- ▶ A single **C-GMA world** is specified at two layers:
 - ▶ Capability layer – unique specification
 - ▶ fixed language to express both capabilities and attributes
 - ▶ mandatory component interfaces
 - ▶ Data-definition layer – multiple different specifications
 - ▶ Data types of published and requested data.
 - ▶ Data-definition language (DDL).
- ▶ Components withing a single world are interoperable
 - ▶ i.e. they co-exist withing the single world, knowing about one another, but not necessarily talking to each other
- ▶ There may be still more independent C-GMA worlds

Summary

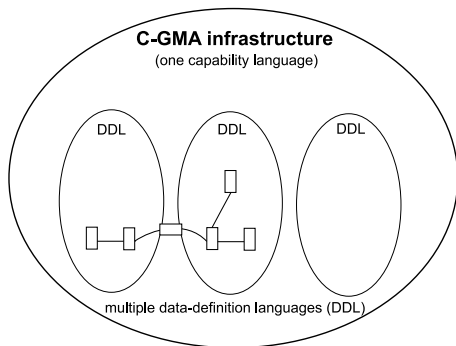

Two layer specification

- ▶ A single **C-GMA world** is specified at two layers:
 - ▶ Capability layer – unique specification
 - ▶ fixed language to express both capabilities and attributes
 - ▶ mandatory component interfaces
 - ▶ Data-definition layer – multiple different specifications
 - ▶ Data types of published and requested data.
 - ▶ Data-definition language (DDL).
- ▶ Components withing a single world are interoperable
 - ▶ i.e. they co-exist withing the single world, knowing about one another, but not necessarily talking to each other
- ▶ There may be still more independent C-GMA worlds

Two layer specification

- ▶ A single **C-GMA world** is specified at two layers:
 - ▶ Capability layer – unique specification
 - ▶ fixed language to express both capabilities and attributes
 - ▶ mandatory component interfaces
 - ▶ Data-definition layer – multiple different specifications
 - ▶ Data types of published and requested data.
 - ▶ Data-definition language (DDL).
- ▶ Components withing a single world are interoperable
 - ▶ i.e. they co-exist withing the single world, knowing about one another, but not necessarily talking to each other
- ▶ There may be still more independent C-GMA worlds

Capability vs. data-definition language

- ▶ Typical DDL is native language of current GMA implementation.
- ▶ Bridge components “speaking” in two DDL are expected.

Summary

Capability and attribute languages

- ▶ One common language for all components in a given C-GMA world.
- ▶ Capability language requirements:
 - ▶ Express both component capabilities and data attributes.
 - ▶ *Component matching* operation
 $[P_{CAP}, C_{CAP}] \rightarrow$ [can communicate each other?]
 - ▶ *Attribute matching* operation
 $[Data_A, P_{CAP}, C_{CAP}] \rightarrow$ [can handle this data?]
- ▶ Two proposals: one based on XML and XPath, second on ClassAds.

Considered capability language definitions

- ▶ XML and XPath
 - ▶ Attributes and capabilities are expressed as XML documents.
 - ▶ Constraints – XPath expressions on merged documents.
- ▶ ClassAds (Classified Advertisements)
 - ▶ Developed for description of jobs and computing elements in Condor.
 - ▶ Symmetric expression of properties.
 - ▶ Extensible – attributes needn't be defined a priori.
 - ▶ Mutual constraints – using “Requirements” expressions.

Capability
languages

XML based
ClassAd based

Summary

Capability language based on XML

- ▶ $Data_A$, P_{CAP} , C_{CAP} expressed as XML documents.
- ▶ Such XML document may contain:
 - ▶ Static values (elements `<cap>` and `<attr>`).
 - ▶ Requirements – XPath expression evaluated in context of compound XML document (element `<req>`).
- ▶ Explicit and implicit requirements.
 - ▶ Explicit requirements – `<req>` element containing XPath expression.
 - ▶ Implicit requirements – shortcut for mutual equality test.
 - ▶ Additional attribute `common-cap` for `<cap>` element.
 - ▶ Requirement of compliance with named party in appropriate element (referenced by value of the attribute).

Capability language based on XML – example

Producer capabilities

```
<producer>  
  <cap name="protocol" common-cap="consumer">https</cap>  
</producer>
```

Consumer capabilities

```
<consumer>  
  <cap name="protocol" common-cap="producer">https</cap>  
  <cap name="securityLevel">5</cap>  
</consumer>
```

Data attributes

```
<data>  
  <attr name="minSecLevel">4</attr>  
  <req test="consumer/cap[@name='securityLevel'] >=  
    data/attr[@name='minSecLevel']" />  
</data>
```

ClassAd based

Summary

Capability language based on XML – matching

- ▶ $Data_A$, P_{CAP} , C_{CAP} documents merged together into a single XML document
- ▶ XPath expressions evaluated in the context of its root element.
- ▶ All the `<req>` elements to be evaluated to true.

Capability languages

XML based

ClassAd based

Summary

Capability language based on ClassAds

- ▶ $Data_A, P_{CAP}, C_{CAP}$ expressed as ClassAd's
- ▶ ClassAd may contain
 - ▶ Static values – attributes and capabilities.
 - ▶ Requirements – logical expression; exact syntax and evaluation functions given by ClassAd implementation
- ▶ Matching done in the context of nested ClassAd

Composed ClassAd

```
{ Producer = {  
  ...  
}  
  Data = {  
    ...  
  }  
  Consumer = {  
    ...  
  }  
}
```

- ▶ References to other ClassAds can be used.
- ▶ All requirements expressions must evaluate to true.

Capability language based on ClassAd – example

Producer capabilities

```
{ Protocol = {http, https}; }
```

Consumer capabilities

```
{  
  Protocol      = {https};  
  SecurityLevel = 5;  
  Requirements  = member(Protocol, .Producer.Protocol);  
}
```

Data attributes

```
{  
  MinSecLevel = 4;  
  Requirements = (.Consumer.SecurityLevel >= MinSecLevel);  
}
```

Summary

Summary

- ▶ C-GMA proposal to address GMA drawbacks
- ▶ Formalization of C-GMA concepts into exact requirements on the two-layer specification
 - ▶ C-GMA interaction phases (matching vs. claiming)
 - ▶ capability language requirements
- ▶ Proposal of two specifications (XML and ClassAd)
- ▶ Proof-of-concept implementation (ClassAd base matching)
- ▶ Proposal for distributed registry based on Content based publish/subscribe messaging systems.
